# THE RIGHT HON'BLE SIR MOUNTSTUART ELPHINSTONE GRANT DUFF, LATE COVERNOR OF MADRAS, GCSI, GIE, FRS, MA, &C, &C

HONORABLE SIR,

The present volume, the first of a new series of Madras Observations, was intended to have been issued long before your retirement from the high and distinguished office of Governor of Madras, and was by your kind permission to be specially dedicated to you, whose discerning, enlightened and liberal views in regard to the encouragement of science, alone enabled me to commence publication, by the removal of certain arbitrary and suppressive restrictions which have prevented me and my predecessors from attempting anything of the kind for considerably more than thirty years past

Without prompt publication of results, scientific researches in general, and above all astronomical observations, are comparatively useless. I came to India deeply impressed with this view, and with the full intention of bringing out an innual volume, and now that you Sir have rendered this possible, and I have every reason to feel assured that your successors in office will continue the valued privilege which you first saw fit to concede to the Madias Astronomer, m, the right of distribution of his publications, enjoyed by every other astronomer in the world but so long disallowed at Midras, the one Observatory of India will, I hope, speedily recover its prestige and remain an enduring evidence of one of the many benefits conferred upon Southern India, during your regime as Her Majesty's representative at Madias

With grateful recollections of past kindness and best wishes for your health, happiness and future well earned distinctions,

I remain, Honorable Sir,
Your most obedient Servant,
N R POGSON

#### INTRODUCTION

Meridional observations were commenced at the Madras Observatory on January 9th, 1793, with a little twenty inch transit instrument, by Stancliff. and a twelve inch altitude and arimuth instrument, by Troughton, neither of them bearing an object glass of so much as an inch and a half in aperture With these diminutive appliances the work of the Observatory was carried The records of the first nineteen years were simply on until the year 1829 copied out and transmitted to the Honorable Board of Directors of the East Those from 1812 to 1825 were published in two bulky India Company folio volumes, but consisted only of unreduced observations of the Sun, Moon, old planets and brighter fixed stars These two volumes were published by the Honorable Company's Astronomei, Mi J D Goldingham, as Volumes 31d and 4th, with a view to the previous records being subsequently printed, an arrangement which however was never carried out

An important step in the history of the Observatory was made in the year 1830, when a five foot Transit Instrument and a four foot Mural Circle, both by Dollond, with object glasses of nearly four inches aperture, were elected under the superintendence of Mr T G Trylor, one of the most able and energetic astronomers of his day. With these instruments, the celebrated "Madras Catalogue," containing positions of 11,015 stars reduced to the Epoch 1835, was accomplished between the years 1831 and 1843, and in spite of its weakest points, large instrumental errors of an unexpected nature in the Mural Cucle, which Mr Trylor did his best to eliminate before printing his final catalogue, its value at the present date may be inferred from the cucumstance of a new edition being now called for by Europe in astronomers It is scaledly necessary to mention that I shall respond to this call with great pleasure as soon as the results of my own labors have been laid before the world, and time permits of the investigation of the remaining errors, both casual and systematic, which still require correcting in the former catalogue The addition of the mean dites of obscivation in each co ordinate, which will of course entail reference to every individual observation upon which the final star positions are based, is also a matter of such importance that there could be no excuse for its omission in case of a second edition of the Catalogue.

The Transit Instrument and Mural Circle were next employed, between 1849 and 1852, in the revision of 1440 stars of the British Association Cata logue, under the direction of Captain W S Jacob, Bombay Engineers, the results being published in Vol VIII of the second series of Madras Obser vations

A considerable number of star observations, made with the same instruments between 1853 and 1858, under the superintendence of Captain Jacob and of Major W K Worster, Madras Artillery, but only partially reduced to apparent places, will, when completed, form another catalogue of about 2,200 stars, for the epoch 1855 A selection of 317 of these stars, suspected of large proper motion, was printed in the "Memoirs of the Royal Astronomical Society", Vol XXVIII

There are also 1,331 observations of the Sun, 345 of the Moon, 1,680 of the principal planets and 333 of various minor planets, made with the old instruments during the same years, in continuation of those given in Volume 7 of the "Madras Astronomical Observations" awaiting publication

It is now about forty years since the Astronomer Royal (then Prof G B Any) introduced a most important change in regard to meridian instru ments, by suggesting a Transit Circle for the Royal Observatory in place of the two separate instruments hitherto employed for determining the absolute Right Ascensions and Polar Distances of celestial objects at Greenwich advantages of having both co ordinates observed at the same time and by the same person, are so obvious, that it is surprising the old practice was so long endured by astronomers The Royal Observatory was supplied with a magnificent Transit Circle in 1850, which was brought into use the following year, the object glass of its telescope being eight inches and its divided circle A fac simile of the Gieenwich instrument, subsequently six feet in diameter supplied to the Cape Observatory, was first used there in 1855 however, in 1852, Mr R C Carrington of Redhill, had a Transit Circle con structed for him by Messis Tioughton and Simms, similar in all essential points to the new one at Greenwich, and divided by the same exquisite machi nery, but with a five-inch object glass and a forty two inch circle instead of the much larger and more costly size adopted at the Royal Observatory no longer required at the Redhill Observatory this fine instrument was ic moved to the Radcliffe Observatory, at Oxford, in 1861, and has been used there ever since

BUILDINGS

In the year 1855, by the liberality of the Board of Directors of the Honorable East India Company, a new Transit Circle, similar to Mi Cairing ton's, was ordered of Messrs Troughton and Simms, upon the recommendation of Captain Jacob The general superintendence of its construction was kindly undertaken by Mr Carrington, who, in consultation with its able makers, advised such alterations in its various details as the experience of his own instrument had led him to consider advisable. The Transit Circle reached Madras in March, 1858, only a month before Captain Jacob's departure, and although orders were immediately issued for its erection, unforcseen difficulties and above all frequent changes in the direction of the Observatory, prevented it from being ready for use until four yours after its arrival

Similar instruments have since been supplied by the same eminent firm to Melbourne, Sidney and many other observatories, both public and private, at home and abroad. The description already given of any one of these instruments is so nearly applicable to all the others that the following brief details of the Madras Transit Circle may seem to many supererogatory, especially as the instrument has now been in constant use for nearly a quarter of a century

#### BUILDINGS

These consist of two blocks,—one comprising the old Observatory with its more accent additions, a long, low, narrow structure, extending 196 feet from East to West, by 25 from North to South, the other, the residence of the Astronomer, from south east, about 120 yards south west of the former, and covering a space of 75 by 50 feet. The original Observatory, built in 1792, consisted of a single room, 40 feet long by 20 broad and 15 high inside, with massive walls, over two feet in thickness. The floor rests on beams supported entirely by the walls and detached from the instrumental basement, which consists of a solid pyramidal mass of misoiny, 37 feet long by 6 feet wide at its upper surface, 6 feet in depth, and 45 feet long by 12 feet broad below, probably little less firm or massive than a solid rock A conical granute pict rests on the centre of this mass, of similar dimensions 4 feet in diameter at its base, tapering up to 2 feet at its total height of 18 feet, and weighing certainly over ten tons. This was the pier originally provided for the little 12 inch alt-azimuth by Troughton, while the small Transit by Stanchiffe and the Transit clock, both rested on granite supports

each weighing about  $2\frac{1}{2}$  tons. When Mr Taylor replaced the small instruments by the Dollond Tiansit and the Mural Circle in 1830, they were fixed on stone piers, the former as far east and the latter as far(to the) west as the basement would allow, on opposite sides of the great central conical frustum, which was retained in position as a huge counterpoise, though no longer used as a support for any instrument

The present Meridian Circle occupies the same position as Mi Taylor's Transit instrument, looking through the same slits in the 100f and walls, which have however been made 22 inches wide instead of only 15 as formerly Two blick piers were first erected for its reception, but these were condemned by Major Worster, in January 1859, and were replaced by excellent granite ones, under Major Tennant's superintendence, in 1860. Each of these piers measures  $4\frac{1}{2}$  reet by 2 and rises 4 feet above the floor of the room. Four composition blocks, each  $4\frac{1}{4}$  feet long by 2 wide and 2 feet 2 inches high, were sent out with the new instrument from England, and on two of these, sui mounting the granite base piers, rests the Meridian Circle, with its pivot centres 6 feet 2 inches from the floor. The other two composition blocks or cap stones support the counterpoise airangements and raise the piers to a total height of 8 feet 4 inches. The clear space between the piers for the observer is 39 inches.

Want of proper instructions, or possibly the loss of such if sent, in regard to the cap stones, caused much difficulty and delay in the erection of the instrument, as if placed in position as they were sent out, the pivots would have been built into two 12-inch square holes, inaccessible even for cleaning and oiling, while the instrument could never have been lifted so much as six inches out of its bearings, whatever alterations or repairs might at any time become necessary. Two slices of  $9\frac{1}{2}$  inches thickness were accordingly cut out of the middle of each cap stone and these were afterwards found very useful in overcoming another difficulty of construction which will be described further on

About the year 1845, when the Magnetical Establishment was removed to the Observatory, the old transit room received considerable extensions, rendered necessary for the accommodation of the additional instruments and assistants transferred to the care of the Government Astronomer Eastward was added, first, a covered passage, 20 feet long by 8 broad, leading to the Dip circle 100m, which measured 16 feet by 26 feet, next a magnetic room,

PUII DINCS VII

45 feet by 15 feet, in which the Bifilar, Vertical Force and Declination Magnetometers were placed and read hourly up to March 1861, and third, a small Transit-theodolite room, 16 feet by 12 feet, used in connection with the Declination Magnetometer and as a computing room for the head magnetical Assistant. About 30 feet more enstward stands a small detached room, 22½ feet by 15 feet, used only for periodical determinations of the absolute Horizontal Force, by means of the usual deflexion apparatus supplied to all the magnetical observatories started upon the recommendation of the Royal Society in the year 1841

Westward of the old transit room were added two small rooms, each 20 feet by 15 feet, the first being used as a computing and manuscript room and the other as a store room for instruments and other property not in actual use

In the year 1872 three additional rooms for celestial photography were hurrically run up on the roof over the Transit Circle room, just in time to secure photographs of the annular cclipse of the Sun on June 6th of that The fine silver glass nine inch reflector by John Browning, used by year Colonel J F Tennant, at Guntoor, on the occasion of the total solar eclipse on August 18th, 1868, having been altered, repuied and sent to Madias by the advice of the Astronomer Royal in 1871, for use at Avenashi in the Coimbatoic District, during the next total eclipse which India was privileged to witness on December 12th, 1871, was afterwards brought to Madras and mounted upon the large granite conic il pier before mentioned, a room, 21 feet by 15 feet, being built to enclose it Aflit sliding shutter was provided, which when rolled off westward, left a square opening of 10 feet, giving the reflector a fair command of the sky except near the horizon where it was never likely to be used for photographic purposes Two small rooms adjoining, one dark for developing and the other for printing and other purposes, were also prepared in time for the annular eclipse in 1872. Very complete and convenient arrangements for securing colestial photographs were made, ostensibly with a view to the approaching Transit of Venus, on December 8th, 1874, and the Browning reflector was in readiness for that important event, but unfortunately cloudy weather prevented any photographs from being taken and the telescope was dismounted and sent to Calcutta, in compliance with orders from the Government of India, in February 1875

A small portable equatorial, with a 31-inch object glass by Dollond, has — - - e since been placed in the reflector-room and is occasionally used for casual

phenomena, such as eclipses or occultations, but all photographic operations were of course stopped by the removal of the reflector. The recent wonder ful advances in celestial photography may render the renovation and equipment of this part of the observatory a very important step in regard to observations in the near future.

The house, originally provided for the Astronomer's use only, is a still older and more substantial building than the Observatory proper already des cribed, and much of it is now given up for purely official purposes tains in all eighteen rooms, eight on the ground floor, seven on the first The ever increasing and already valuable and floor and three on the roof extensive Library occupies two rooms on the ground floor, and in these also are placed the electrical clock and telegraphic appliances used for giving true time to the local shipping and generally to all parts of India step of the north east door of the Libiary is a bench mark of the G T Sur vey of India and is 22 feet above mean sea level The private office of the Astronomer is immediately over the Library, and on the roof are, a small Anemograph room,  $10\frac{1}{2}$  feet square, a 16 foot circular room with an excel lent revolving dome, containing a fine eight inch Equatorial by Messrs - -Troughton and Simms, and another, slightly smaller but similar room, for the six inch Equatorial by Messis Lerebours and Secretan, formelly used to such good purpose by Captain Jacob in measurements of double stars and of Saturn's satellites

Photographs or drawings of the buildings and of the chief instruments were intended to have been given in this volume, but are unavoidably deferred for the present

#### THE MERIDIAN CIRCLE

This fine instrument, as already stated, was made by Messrs Troughton and Simms, in consultation with the late Mi R C Cairington, and its gene ral excellence has proved most satisfactory. The clear aperture of the object glass is  $5\frac{1}{2}$  inches and its focal length about 50 inches, the magnifying powers of the eye pieces being very nearly as engraved on each, vii, 105, 147 and 230. The middle power has been used throughout. A Bohnen berger's eye piece, power 106, was also supplied for determinations of the nadii point and level error

The horizontal axis consists of a central 12 inch cube and two cones,

each ten inches in diameter at the cube and in one casting of gun-metal therewith, bearing at their extremities the pivots, also of gun metal, which are 3 inches in diameter and rest in brass Y's, adjustable vertically only by screw-motion, any change in azimuth requiring the forcible bodily movement of the east pivot support by means of double wedges, but such adjustment has only been once needed since the instrument was finally mounted in 1862. The pivots and Y's are so well boxed in with close fitting brass covers that dust and moisture are effectually excluded

The two ends of the telescope are each screwed to the cube by twelve stout There are two nearly similar gun metal 42 inch circles, each firmly secured by means of leight screws to truly faced flanges, attached to the conical axes on opposite sides of the cube The clear space between the two The eastern circle is coarsely divided, to 10' only, circles is just 30 inches for setting, and is also intended as a handle for turning the instrument nound It is clipped by two clamps, with slow motions and tangent rods, which have generally been used for making bisections in preference to the micrometer of the eyepiece, ever a fruitful source of error in polar distance The western circle carries a rim of gold, inclined at a level determinations of about 12° to the plane of the circle to facilitate reading and illumination, and is divided with Messis Troughton and Simm's well known precision into The divisions are read off by six microscopes of very considerable 5' 5paccs magnifying power, so placed as to bring their micrometer eyepieces within a cuicle of 30 inches diameter and for the lower microscope to read zenith-dis Each microscope micrometer screw moves a pair of close parallel wires, the nearest division of the limb being brought midway between them instead The divided circle is enclosed in a light of being bisected by cross wires open work box to shield it from accidental injury by the observer

The greatest source of delay and difficulty in mounting the instrument was in regard to the fixing of the six microscopes. It was(obviously) intended that they should be placed as they now are, for the lower one to read courth distances, and the hole for it to look through was drilled in the lower part of the western pier in readiness. This however caused the upper micro scope, in the cap stone above, to come immediately above the flame of an argand lamp, provided for lighting up the field of view, or the wires in a dark field, and for the general illumination of the limb opposite to each microscope. It was soon found that the much smaller flame of a thin flat wick gave ample illumination for the limb and also for the wires in a bright field, though not

sufficient for the satisfactory use of bright wires in a dark field. With one of the slices cut out of the cap stones, as mentioned on page vi, a conical frustum, of 24 inches base and 19 at its face, was attached to the western pier, projecting 6 inches from it, and with a continuation of the 12-inch square space left for the pivot supports, through its centre. By placing a small lamp therein, with a bent chimney to carry off all smoke and as much heat as possible, the difficulty was at last overcome, certainly not as arranged by Messis. Troughton and Simms but quite effectual for the purpose. The conical projection lies between the micrometers, serving as a protection to them against possible injury, but is neither in the way nor in the least unsightly, and no one seeing the instrument for the first time would imagine for a moment that it was any addition to or departure from the original design. The light of the small lamp is guided and condensed by a frame of seven lenses, a large central one for illuminating the field, and six smaller ones for distributing it where required upon the divided limb under each microscope

Two pairs of brass arcs had been provided for the support of the other four microscopes, one pair for the eyepieces and micrometers on the outside western face of the prer, and a larger pair, to bear the objectives on its eastern or inner side, apertuiss being also left in the composition stones for the long tubes connecting the eyepieces and their objectives, but in order to fix the upper microscope after cutting out a  $q_{\frac{1}{2}}$  inch slice just where it had to come, two more similar metal arcs had to be cast and made up here Considering the difficulty of getting anything of the kind done in Madras in those times, it would have been much better for Messis Troughton and Simms to have sent out a skilled mechanic to assist in the erection of the instrument, but it fortunately happened, that in September, 1861, a German Mathematical Institument maker, the late Mr F Doderet, was sent out by the Right Honorable, the Secretary of State for India, to start workshops for the repair of levels, theodolites, &c, for the Public Works Department, and as no place, plant or assistants were prepared for him, I was readily granted the benefit of his services for six months Major Tennant, when in charge of the Observatory had purchased for Government an excellent lathe, by Holtzaffel, and with it and a supply of other tools from the Aisenal, we set vigorously to work and got the Transit usable for time determinations by the end of the year, and all the modifications required in the microscope arrangements finished in May 1862, when complete observations were first steadily commenced

Heavy counterpoises, with their fulcia resting on inch thick iron plates, crossing the cap stones, relieve the Y's of most of the weight of the instrument, by means of two pair of 5 inch friction rollers, applied to grooves on the axis between the circles and pivots, small additional weights sufficing to lift it out of its bearing for cleaning and oiling. The residual pressure of the pivots upon each Y is about 10 or 12 lbs

A finder, 15 inches in length and 11 in sperture was added to the teles cope, presumably for estimating the magnitudes of the brighter stars but its utility for that or any other purpose is very questionable

The telescope eyepiece was provided with a system of seven vertical and one horizontal spider lines, moveable each way by micrometer screws of practically the same thread. The single horizontal line was replaced by a close pair, about 12" apart, and bisections have throughout been made by bringing stars exactly midway between the two when crossing the centre vertical wire. For observations of Mars especially, the estimated equality of the segments above and below, was unquestionably better than tangential contacts of a single line with either north or south limb

For collimating, two 35 meh telescopes with 21 meh object glasses, are mounted on piers, level with the centre of the Transit circle, inside the room, and at a distance of 57 mehes from the object glass of the instrument when turned to either the north or south horizon. The central cube is pierced by two 4 meh circular apertures, so that the wires in each collimator can be seen through the other when the circle reads 180°. The south collimator micro meter moves horizontally, for fixing an approximate meridian line, and the north one vertically, so as to give a nearly horizontal line for flexure determinations. Having only native assistants for observers and considering therefore that extreme simplicity would ensure the safest results, I did not adopt the Greenwich pattern of wires, but preferred simple crosses, that in the north collimator being arranged as in the sign x and that in the south collimator as a +, which I thought better suited to those who had to use them

Upon my minval at Madras I found the collimators placed outside the Observatory in small square detached nooms, twenty feet further from the Transit circle than they now me. This was far more convenient as regarded space inside, and would have permitted of reflexion observations being taken much lower, had such been possible and urgently desirable, but I soon

found upon trial, that the passage of the visual rays through three strata of air of very unequal temperatures, caused the wires to appear so faint and tremulous that I gladly removed the collimators inside the Observatory, as Mr Carrington's were placed at Redhill, and the result was all that could be expected or desired

A convenient transit observing seat runs on six rollers, between the circle piers, from one collimator pier to the other, and on the instrumental basement, a foot below the boarded floor, in which are five hinged trap doors, is a railway for two moveable reflexion troughs, besides a fixed circular one, vertically below the centre of the Transit circle, for use with the Bohnenberger eyepiece, for nadir point and level error determinations

#### CLOCKS AND CHRONOGRAPH

One of those rare and matchless old clocks, by Shelton, with a gridiron pendulum the compensation of which as nearly approaches perfection as possible, was found in India when the Observatory was first started in 1792, and is to this day by far the steadiest timekeeper in the place. It was used as the transit clock till 1859, when it was replaced by a new one by Dent, with a mercurial pendulum, of the best modern construction, but certainly no improvement upon the old one except in its far louder and more convenient beat. Some of the mercury was accidentally spilt in setting up the new clock and though more was added to replace the missing quantity, its compensation has never yet been so satisfactory as that of the old Shelton, which has since been used with the principal Equatoreal. The performance of the Dent transit clock has, however, been good throughout and no better could be desired as a standard sidereal regulator.

A curious old clock, by Haswall, used by Mr Goldingham in his pendulum experiments in 1821, with a mainspring instead of a weight and a very peculiar double escapement, was formerly used with the old mural circle and was most capricious in its daily rate. The escapement being simplified and the spring exchanged for a barrel and weight, it has been used with the smaller equatoreal since 1866, and has worked better, though never comparable to the two first named

An excellent mean time electrical clock by Shepherd & Son, was supplied to the Observatory in 1872, and though severely criticized when under trial at the India Store Department for instruments, at Lambeth, it has worked well

enough at Madras It transmits hourly currents, by which a time gun at Fort St George, about three miles distant, is fired at noon and 8 pm. and a semaphore at the Maine Office, a mile further, is dropped at 8 a m and 2 pm, with as few failures as are usually made in time signals clscwhere It also passes alternately positive and negative currents, second by second, for the control of sympathetic clocks, one of which has been going it the Marine Office since 1879, as fairly as could be expected considering its very indifferent treatment ever since it was set up. When first received at Madras, the Shepherd clock had a magnetic contrivance for the daily rectification of its small error, as necessary in all electrical motor clocks, and this was undoubtedly the source of dissatisfaction when on its trial in London, is until it was discarded nothing could be done with the clock here however as a simple gravitation adjustment was substituted, consisting of a small biass weight of 159 grains, which when placed upon a shelf about 18 nuches below the point of suspension of the pendulum makes the clock gain a hundreth of a second per minute, or lose at the same rate when placed on another shelf below the pendulum ju, all irregularities ceased and no further difficulty was experienced

Application was made for a chronograph in 1863, chiefly with a view to carrying out telegraphic longitude operations, and for observations of Mais in opposition for investigation of the constant of solar parallax. A barrel chronograph was specified as being the only kind desired, the time marks being read off with so much more certainty, speed and convenience when in parallel rows on a single sheet than from many yards of a thin paper tape or fillet. My application received no reply at the time, but several years later a French fillet recorder was sent out, too late for the special purposes for which it was wanted and quite unsuitable, even if it had been supplied when asked for

# OBJECTS SELECTED FOR OBSERVATION WITH THE TRANSIT CIRCLE

The objects selected for observation with the new Meridian-circle were, the brighter stars inclusive, down to the 5th magnitude, the moon and moon culminating stars given in the Nautical Almanae, Mais and the stars observed with him at successive oppositions, on the meridian, as well as those used east and west, with the Equatoreal, for parallax investigations, minor planets in opposition, if not under the 10th magnitude, comparison stars used for differential observations of comets and planets from 1861, all known

variable stars, zero stars for maps of those objects in hand, and as many others, not below the 9th magnitude, as time would permit, between 130° and 150° Polar Distance, as determining stars for the zones of the Southern Survey, in extension of the late Prof Argelander's great Northern Survey, which, with that distinguished astronomer's warm approval and advice I had intended to make my chief personal labor at Madras. The very extraordinary opposition met with to this work, from a quarter whence such was least expected, partitioning out in portions to other observatories the work I had undertaken as a whole, compelled me to abandon any participation in its accomplishment at the end of 1863, after it had been fairly commenced in that year

The refusal of European assistance, after I had been authorized to apply to Piof Argelander and Mr Hind to suggest for appointment any well qualified young astronomer either of them might know of as available, was a death blow to the too ambitious programme I had undertaken and an urfore seen justification for my renunciation of the Southern Survey Government and its distinguished chief, Sir W Denison R E, had warmly supported my plea for a German or English assistant, and were so well assured of its being granted, that the plan and estimate for separate quarters in the Observatory grounds, for the accommodation of a Deputy Astronomer, were sanctioned and the foundations actually laid out, before the refusal of the promised help was received from the India Office in London My intention was to have only a small catalogue of stars observed by the native assistants with the Meridian Circle, pending completion of the first few maps of the Southern Survey, and as soon as the approximate catalogues, similar to those of the Bonn "Durchmusterung" were available, to have all the stars they contained observed in zones with the new instrument, just as the "Durchmusterung" itself has been since dealt with by the northern observatories

Finding that the Mendian circle must be used by native observers only, who though good for the slow methodical processes of ordinary mendian observations, could never be entrusted with the more arduous work of zoning, the best course was to increase the former observing list by the addition of as many anonymous stars of more than 120° Polar Distance as could be found, not less than the 8th magnitude. No star was to be observed on less than five nights and all objects of more than ordinary interest on at least ten nights, and this has been adhered to throughout, wherever possible

#### **OBSERVATIONS**

Observations with the Meridian Circle, the results only of which are given in this volume, were almost entirely made by three native assistants, who were as fair observers as could probably be found of their class Assistant, C Sashoo Iyengar, was scrupulously careful and accurate and was warmly commended by every Astronomer, from 1837 up to the time of his death, in March, 1863 He was succeeded by C Ragoonatha Chary, whose better mathematical attainments and general aptitude for science, justified me and my finend, Mr E B Powell, then Director of Public Instruction, and one of the greatest authorities upon the subject of Double Stars, in recom mending him for the honor of election as a Fellow of the Royal Astronomical Society The other native assistant who took part in the meridian observa tions wis T Moottoosawmy Pillay, also a very trusty, painstaking man All three had used the old meridian instruments, but it was not until after more than a year's practice with the new Transit circle that I dare trust them to determine all their own instrumental corrections in the ordinary course of the night observations, though decidedly convinced that it is far better to do so than to make special determinations and interpolate for the required dates, however steady the corrections may be There were such evident personalities between them, that from the first I made each assistant find his own corrections, nearly always being present, until I became assured that it would be safe to entrust them with such manipulations alone The corrections for index and run of the microscopes micrometers were, from the first, found at night, but those for inclination and collimation in the day time, until September 1863 Due allowance being made for diurnal aberra tion, the right ascension micrometer was set to the corrected reading for no collimation, and until April 1863, when the use of the polar distance micro meter was first considered prudent, bisections were made with the tangent rods and slow motions of the clamps Even then it proved a very ques tionable step and was a funtful source of error long after its introduction

Observations were entered, in pencil, in convenient recording books as they were made. The standard barometer, by Newman, supplied by the Royal Society in 1841, and one of two thermometers, verified at Kew, were recorded for refraction reductions, the one used being at either a north or south window, according to the direction of the wind at the time of observation

#### REDUCTION OF THE OBSERVATIONS

These were carried out in folio day books. The originals were bound for preservation in the Observatory, but as in the tropics it seems impossible to ensure that for long, copies were made for safer deposit in England, where they may be readily available for reference whenever desirable

The arrangement of the day books is as follows —

Left side —Polar Distance 12 columns

- 1 —Reference Number
- 2 —Date and Observer
- 3 —Barometer
- 4 —Thermometer
- 5 -Name of Object
- 6 —Deduced Circle Reading 1 e zenith distance counted found through south nadir and north up to 360°, the means of the six microscopes, corrected for index, fun of micrometers, and curvature if not observed at the centre of the field
- 7 —Refractions, computed by "Bessel's Tables" as modified and expanded in an appendix to the Greenwich Observations for 1853
- 8 —Apparent Polar Distance, assuming the latitude as given in the Nau tical Almanac, viz, 13° 4 8" 1 north
- 9 —Reductions to January 1st, using the "Day Numbers" of the Nautical Almanac, and constants calculat ed for every star not in the N A list for the year
- 10 —Mean Polar Distances of Stars
- 11 —Apparent Polar Distance by Ephe meris
- 12 Correction to Ephemeiis

Right side -Right Ascension 17 columns

- 1 —Reference Number
- 2 —Name of Object
- 3 -Number of Wires
- 4 —Estimated Magnitudes
- 5 —Mean of Wires —the clock time of thansit over the mean of the seven wires being meant in all cases, and every object observed over a less number being reduced thereto by the adopted intervals of the wires noted
- 6 —Inclination correction
- 7 —Collimation correction
- 8 —Meridian correction
- 9 —Personal equation of Observer
- 10 —Sum of columns 6, 7, 8 and 9
- 11 —Cornected clock time of transit
- 12 -Clock correction applied
- 13 Apparent Right Ascension
- 14 —Reduction to January 1st, calculated as in column 9 of the Polai Distance page
- 15 —Mean Right Ascensions of Stars
- 16 —Apparent Right Ascension by Ephe meris
- 17 -Cornection to Clock on Ephemeris

The contents of the Observing or Recording books and of the Reduction or Day books are now rarely published except at national Observatories, colonial and private Observatories seldom having either the staff or the funds required for printing such voluminous details, of questionable interest or utility to those who only desire results

The horizontal wires were most carefully adjusted, so that a star brought exactly between them upon entering the field of view was satisfactorily so when quitting it at the opposite side and no correction was therefore required to the very few cases in which a star was not bisected close to the middle transit wire

The value of one revolution of the Polar Distance micrometer, found by biscoting the cross of the north collimator with the close horizontal wires at different settings of the micrometer and reading off the Circle, was 26" 33 Measured by means of coincidences between the wires and their reflected image, it was 26" 37 The mean value, 26" 35 was adopted

The value of one revolution of the Right Ascension micrometer, found in a similar manner, after turning the eyepiece end through 90°, until the close horizontal wires were in a vertical line and then reading off the Cucle when the centre wire was made to bisect the cross of the north collimator at various readings, was 26'' 66=1 771 seconds of time

The intervals of the seven wires from their mean, determined by twelve complete transits of polar stars in 1862, were as follows —

$$+36^{\circ}979 + 24^{\circ}705 + 12^{\circ}351 + 0^{\circ}109 - 12^{\circ}348 - 24^{\circ}697 - 37^{\circ}098$$

The Madras factors for inclination and meridian corrections were found by the following formulæ, the Polai Distance being considered negative for below pole factors

Inclination factor = +0 974+(9 35435) cotan Polar Distance

Meridian factor = +0 226-(9 98861) cotan Polar Distance

The correction for diurnal observation at Madras being 0s 020, for the centre wire + 0s 109, and the zero of collimation having been found by taking the mean of the R A micrometer readings of the centre wire, when bisecting the crosses in the north and south collimators, after they had been adjusted upon each other, we have for my other reading of the R A micrometer

Collimation correction = 1° 771 (zero of coll -adopted reading -0 073)

The reading of coincidence of the centre wire with its reflected image in mercury being taken, we have also,

Inclination correction = 1,771 (zero of coll —coincidence reading)

The small altitude of the pole at Madras renders the observation of stars often impossible at their lower transit. Weather permitting, the Meridian-correction was found by a pair of polar stars, but frequently of necessity from one only, combined with a south star, when of course no other use was made of the observation, beyond that of furnishing the correction for the night. The correction was interpolated when not otherwise determinable

Personal equations were merely used for the convenience of avoiding changes in the local time, for the public signals, as different observers came on The watches usually extended over half a month and the clock errors were never mixed Upon several occasions, when the instrument was in use only as a Transit, before the Circle airangements were completed, I observed a num ber of clock stars intermediate between those of the native assistants, and from comparisons thus obtained, it appeared that they all required negative corrections to their recorded times relatively to my own adopted were, for Sashoo -0° 75, for Ragoonatha -0° 35, and for Moottoosawmy -0° 23 I afterwards found that similar differences in the habits of bisection existed between the native observers and myself, rendering it equally necessary for each one to determine his own corrections for Index and Run, and causing apparent changes in the corrections certainly not due to the instrument, as may be readily seen in the following tables of adopted "Instrumental Corrections", where the numbers enclosed in brackets are the determinations of different observers on the same night

The Nautical Almanac positions of Standard stars were used entirely for finding the clock corrections, a few being rejected for the purpose, especially Sirius and 61 Cygni Whatever corrections are due to the Nautical Almanac stars will therefore affect the Madras Right Ascension throughout

For the determination of the Meridian corrections, as well as with a view to securing data for correction of the assumed latitude, the positions of a number of the brighter stars in the "Catalogue of 164 Stars within 6° of the North Pole", given in Vol XVI of the "Radcliffe Observations" were employed. I preferred using the positions given therein to those of the "Radcliffe Catalogue of Stars for 1845", as they were entirely my own bringing up, under the supervision of my esteemed chief Mr Johnson, then Radcliffe

Observer, who was ever anxiously watchful for the results as the work was in progress

A flexure correction of 1"72 x sin Zenith Distance, was applied provisionally to the Polar Distances in this volume and I regret not having twaited a final value before using such a correction at all

Any investigation of the correction to the assumed latitude before the flexure correction is finally settled would be premature, nor do I think it will be worth while to trifle with partial year to year enquiries now that all the observations for the Catalogue are completed There is good reason to believe that the lititude requires to be increased (Mr Taylor used 9"2 instead of 8" 1 for his "General Catalogue for 1835") and it will be far better to combine all observations taken of each star, above and below pole, when reduced to the epoch 1875, a work which I hope to proceed with as early as other duties will permit, while the next volume is in hand

The Inclination correction was adjusted on each of the first five nights on which the instrument was

used It was afterwards determined about noon, on June 7 9, 12

The Right Ascension micrometer was set to the corrected reading for no collimation except on June 7 when it was left by mistake so as to require a correction of — 014 second

The microscopes were removed on June 23 for a few days during the fastening of a conical stone ring to the western pier between them and the lamp

The microscopes were re adjusted throughout on July 3 and 15

The Clock rate was diminished 0.5 second after the observations on July 31

The Inclination correction was determined usually about noon on June 14 17 20 July 3 10 15 21

28 and August 4

The Right Ascen ion micrometer was set to the corrected reading for no collimation except on June 19 when by a careless mistake it was left seven revolutions wrong and a correction of — 12 40 seconds had to be used

The Inclination correction was determined between noon and 3 PM on January 16 31 February 2 5 13

The Right Ascension micromotor was set to the corrected reading for no collimation except on January
16 when the observer during the second part of the night slightly misplaced it leaving a correction of +001 second

The eye end of the telescope was removed on April 7 to have the polar distance micrometer repaired by Mr F Doderet The collimators and the inclination correction were adjusted.

The Inclination correction was determined between 2 and 7 r M on March 31, April 1, 7 10 15, 16 and May 1

The Right Assertion measurements was get to the corrected reading to the collimator before hereater.

The Right Ascension micrometer was set to the corrected reading for no collimation before beginning to observe

The Inclination correction was determined between 2 and 4 pm on August 31 Sep 16 24

The Right Ascension micrometer was set to the corrected reading for no collimation before beguining to observe up to September 25

The Inclination and Collimation and corrections were determined each night during observing hours by the Assistant on duty from September 26 the Meridian correction also whenever polar stars were available

Sudden and considerable changes in the Index Inclination and Meridian corrections usually occur after heavy rain instances of which may be seen after October 14th and November 30th in the preceding table. Buildings resting upon massive foundations like the Observatory are up heaved as a block and slightly tilted slowly recovering the ositions as the rain leaves the sandy soil by drainage and evaporation. Where the foundation are less solid cracked walls and too frequent collapses are the familiar results of a heavy downpour, as may be noticed after every rainy season in Madras.

The Transit clock rate was again altered 1 second on November 26th

#### SEPARATE RESULTS OF OBSERVATIONS

These, though forming the bulk of the present volume, require but little further explanation than is afforded by the headings of each column

In the second column, Flamsteed's numbers, Bayer's Greek letters, and tamiliar names by which the principal stars are known, have been used in preference to any other designations For other objects, reference is made to "Taylor s Madras Catalogue", to Baily's edition of "Lalande", to the two Cut alogues of "Bessel's Zones", compiled by Weisse, with W B E for the first, containing stars within 15° of the equator, and W B N for the Similarly, the northern and southern catalogues of second or northern one "Angelander's Zones", compiled by Oeltzen, are indicated respectively by O. A. N. Polar stars, used for mendian error, taken from the "Catalague of 164 Stars within 6° of the North Pole", in Vol XVI of the "Radelific Ob a valions", are referred to by their number therein, followed by R P L For the Viriable Stars I have used my own nomenclature, agreed to by Prof. Augelander, Sir John Herschel and other astronomers, when my Atlas of these objects was first fairly taken in hand, nearly thirty years back, in which Prof Argelander's letters, R, S, T, &c, are returned, but the name of the constellation is followed by Vai 1, Var 2, &c, showing thereby the order of proved variability of each star in such constellation. As it is now so many years since this simple method of reference to the viriable stars was first suggested by me, it may be as well to state that it makes no distinction between periodical and temporary stars, those which are subject to more or less regular changes and those which have only once risen to a maximum Thus, in Cussioper, we have Gemma's Nova of 1572, known as B Cussioper Vir 1 a Cassiope i Vai 2, R Cassiope i Var 3, &c In Scorpio ilso, we have, R Scorph Vi 1, S Scorph Vir 2, the two small variables near the cluster 80 Messier, first figured on page 357 of Smyth's Celestral Cycle, T Scorph Var 3, Auter's Nova of 1860, which blazed out apparently in the centre of the cluster itself, and V Scorpii Vai 4, my own Nova of 1863. No 601 of the Lists for 1863 on pages 99 and 152 of this volume

The estimations of magnitude made by Ragoonatha Chary are fairly accordant with Argelander's scale and are generally within a quarter of a magnitude, but those of Moottoosawmy, who affected tenths, were much less certain

ĸ.

### MEAN POSITIONS OF STARS OBSERVED IN EACH YEAR

In the annual lists of Mean Positions of Stars, only complete observations are included, so as to render the mean date the same for both co ordinates. The numbers and references for the stars observed are the same as in the Separate Results. When magnitudes were noted, the mean of the estimations is given, but when no figure stands in the column of Estimations it must be understood that the magnitude entered is taken, from Argelander's "Uranometria Nova", from the two Radcliffe Catalogues, or from some other trustworthy source

The Right Ascensions and Polar Distances are the simple means of the separate results, the latter being still only provisional and subject to further small changes in regard to the corrections for flexure and assumed latitude

The tables on the four following pages, showing the excess of the Madras Mean Positions above those given in the Nautical Almanac for each year, render it certain that the Polar Distances will require some further small correction before being formed into a final general catalogue

The annual precessions were computed by means of the formulæ given in the Nautical Almanac, in which the co efficients of Prof Peters were adopted, and the secular variations are the differentials of the precessions multiplied by 100, the variations of m and n being duly taken into account

The proper motions, when not otherwise mentioned, are from the well-known lists published by Mr Main, in the 19th and 28th, and by Mr Stone, in the 33rd volumes of the "Memoirs of the Royal Astronomical Society" When from any other source the authority is given in the foot notes "Greenwich Catalogue" refers to the most recent of the five Greenwich Catalogues in which the star was found, and "Stone's Catalogue" to the great "Cape Catalogue of 12,441 Stars"

## OTHER OBSERVATIONS WITH THE MERIDIAN CIRCLE

The observations given in this volume relate only to the fixed stars During the three years however, 163 observations of the Moon, 66 of Mars and 195 of 37 Minor Planets were made with the Meridian Circle, all of which await publication in a volume of Planetary and Cometary discoveries and observations, made chiefly with the equatoreals but supplemented by the Meridian Circle when any planet was not much below the 10th magnitude and was therefore observable in the illuminated field of that instrument

37—39—Comparison stars used with Mars in opposition in 1862 for investigation of the constant of Solar Parallax

42—R Piscum Var 1—Period, 345 days

Range 7 5 to 12th magnitude

66—Mira Ceti Var 1—Period 331 days

Range 2nd to 10th magnitude

Observed with the Madras Meridian Circle in that Year
